THE 2-ADIC VALUATION OF STIRLING NUMBERS

TEWODROS AMDEBERHAN, DANTE MANNA, AND VICTOR H. MOLL

Abstract. We analyze properties of the 2-adic valuations of $S(n,k)$, the Stirling numbers of the second kind. A conjecture that describes patterns of these valuations for fixed k and n modulo powers of 2 is presented. The conjecture is established for $k = 5$.

1. Introduction

Divisibility properties of integer sequences have long been objects of interest. In modern language these are expressed in terms of p-adic valuations: given a prime p and a positive integer m, there exist unique integers a, n, with a not divisible by p and $n \geq 0$, such that $m = ap^n$. The number n is called the *p-adic valuation* of m. We write $n = \nu_p(m)$. Thus, $\nu_p(m)$ is the highest power of p that divides m. The graph in Figure 1 shows the function $\nu_2(m)$. Here and elsewhere in this paper we connect succesive points in the graph in order to visually convey the rises and drops of the sequence.

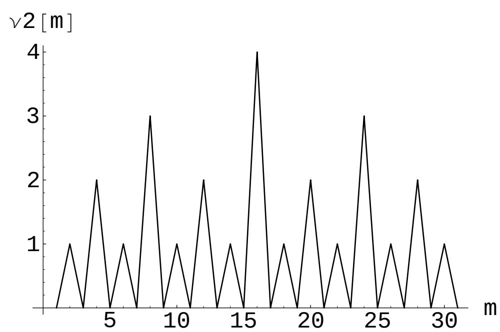

Figure 1. The 2-adic valuation of m

A celebrated example is due to Legendre [8], who established

$$\nu_p(m!) = \frac{m - s_p(m)}{p-1}. \tag{1.1}$$

Here $s_p(m)$ is the sum of the base p-digits of m. In particular,

$$\nu_2(m!) = m - s_2(m). \tag{1.2}$$

1991 *Mathematics Subject Classification.* Primary 11B50, Secondary 05A15.
Key words and phrases. valuations, Stirling numbers.

The reader will find in [7] details about this identity. Figure 2 shows the graph of $\nu_2(m!)$ exhibiting its linear growth. The binary expansion of m is $m = a_0 + a_1 \cdot 2 + a_2 \cdot 2^2 + \ldots + a_r \cdot 2^r$, with $a_j \in \{0, 1\}$, so that $2^r \leq m \leq 2^{r+1}$. Therefore $s_2(m) = O(\log_2(m))$ and we have

$$\lim_{m \to \infty} \frac{\nu_2(m!)}{m} = 1. \tag{1.3}$$

Figure 3 shows the error term $s_2(m) = m - \nu_2(m!)$.

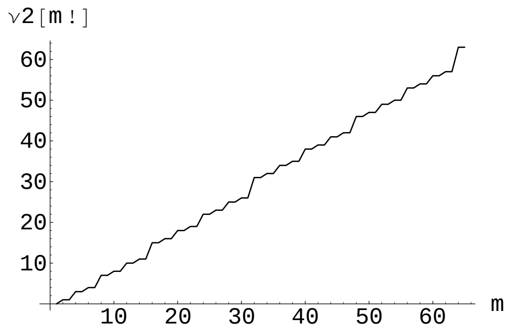

FIGURE 2. The 2-adic valuation of $m!$

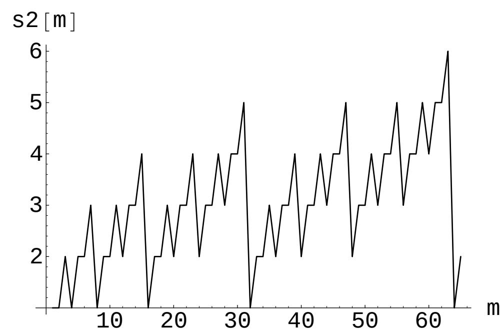

FIGURE 3. The error $\nu_2(m!) - m$

Legendre's result (1.2) provides an elementary proof of Kummer's identity

$$\nu_2\left(\binom{m}{k}\right) = s_2(k) + s_2(m-k) - s_2(m). \tag{1.4}$$

Not many explicit identities of this type are known.

The function ν_p is extended to $\mathbb{Q}$ by defining $\nu_p\left(\frac{a}{b}\right) = \nu_p(a) - \nu_p(b)$. The *p-adic metric* is then defined by

$$|r|_p := p^{-\nu_p(m)}. \tag{1.5}$$

It satisfies the ultrametric inequality

$$|r_1 + r_1|_p \leq \text{Max}\left\{ |r_1|_p \, , \, |r_2|_p \right\}. \tag{1.6}$$

The completion of $\mathbb{Q}$ under this metric, denoted by $\mathbb{Q}_p$, is the field of p-adic numbers. The set $\mathbb{Z}_p := \{x \in \mathbb{Q}_p : |x|_p \leq 1\}$ is the ring of p-adic integers.

Our interest in 2-adic valuations started with the sequence

$$b_{l,m} := \sum_{k=l}^{m} 2^k \binom{2m-2k}{m-k}\binom{m+k}{m}\binom{k}{l}, \tag{1.7}$$

for $m \in \mathbb{N}$ and $0 \leq l \leq m$. This sequence appears in the evaluation of the definite integral

$$N_{0,4}(a;m) = \int_0^\infty \frac{dx}{(x^4+2ax^2+1)^{m+1}}. \tag{1.8}$$

In [2], it was shown that the polynomial defined by

$$P_m(a) := 2^{-2m}\sum_{l=0}^{m} b_{l,m}a^l \tag{1.9}$$

satisfies

$$P_m(a) = 2^{m+3/2}\,(a+1)^{m+1/2}N_{0,4}(a;m)/\pi. \tag{1.10}$$

The reader will find in [3] more details on this integral.

The results on the 2-adic valuations of $b_{l,m}$ are expressed in terms of

$$A_{l,m} := \frac{l!\,m!}{2^{m-l}}b_{l,m}. \tag{1.11}$$

The coefficients $A_{l,m}$ can be written as

$$A_{l,m} = \alpha_l(m)\prod_{k=1}^{m}(4k-1) - \beta_l(m)\prod_{k=1}^{m}(4k+1), \tag{1.12}$$

for some polynomials α_l, β_l, with integer coefficients and of degree l and $l-1$ respectively. The next remarkable property was conjectured in [4] and established by J. Little in [10].

Theorem 1.1. *All the zeros of $\alpha_l(m)$ and $\beta_l(m)$ lie on the vertical line $\operatorname{Re} m = -\frac{1}{2}$.*

The next theorem, presented in [1], gives 2-adic properties of $A_{l,m}$.

Theorem 1.2. *The 2-adic valuation of $A_{l,m}$ satisfies*

$$\nu_2(A_{l,m}) = \nu_2(\,(m+1-l)_{2l}\,) + l, \tag{1.13}$$

where $(a)_k = a(a+1)(a+2)\cdots(a+k-1)$ is the Pochhammer symbol.

The identity

$$(a)_k = \frac{(a+k-1)!}{(a-1)!} \tag{1.14}$$

and Legendre's identity (1.2) yields the next expression for $\nu_2(A_{l,m})$.

Corollary 1.3. *The 2-adic valuation of $A_{l,m}$ is given by*

$$\nu_2(A_{l,m}) = 3l - s_2(m+l) + s_2(m-l). \tag{1.15}$$

There are many other examples of 2-adic valuations considered in the literature. H. Cohen [6] has discussed the sum[1]

$$C_k(n) := \sum_{j=1}^{n} \frac{2^j}{j^k}. \tag{1.16}$$

These are the partial sums of the polylogarithmic series

$$\text{Li}_k(x) := \sum_{j=1}^{\infty} \frac{x^j}{j^k}. \tag{1.17}$$

The series converges in $\mathbb{Q}_2$ provided $\nu_2(x) \geq 1$. Cohen proves that

$$\nu_2(C_1(2^m)) = 2^m + 2m - 4, \quad \text{for } m \geq 4, \tag{1.18}$$

and

$$\nu_2(C_2(2^m)) = 2^m + m - 1, \quad \text{for } m \geq 4. \tag{1.19}$$

The graph in Figure 4 shows the linear growth of $\nu_2(s_1(m))$ and Figure 5 presents the error term $\nu_2(s_1(m)) - m$.

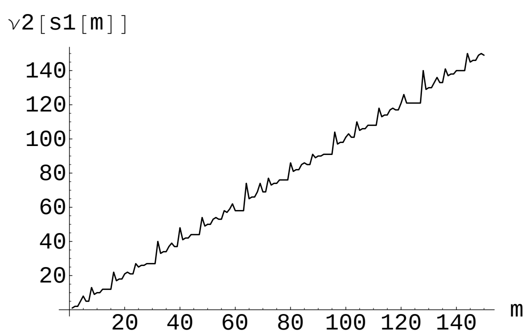

FIGURE 4. The 2-adic valuation of $C_1(m)$

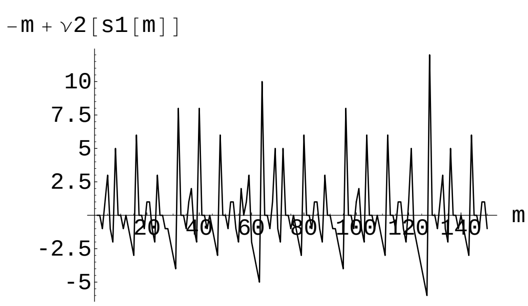

FIGURE 5. The error $\nu_2(C_1(m)) - m$

[1]Cohen uses the notation $s_k(n)$, employed here in a different context.

In this paper we analyze the 2-adic valuation of the Stirling numbers of the second kind $S(n,k)$, defined for $n \in \mathbb{N}$ and $0 \leq k \leq n$ as the number of ways to partition a set of n elements into exactly k nonempty subsets. The next figures show the function $\nu_2(S(n,k))$ for fixed k. These graphs indicate the complexity of this problem.

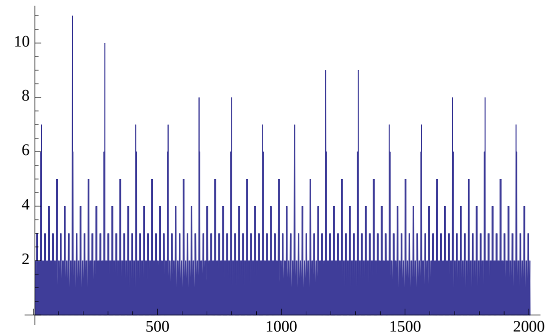

FIGURE 6. The data for $S(n,5)$

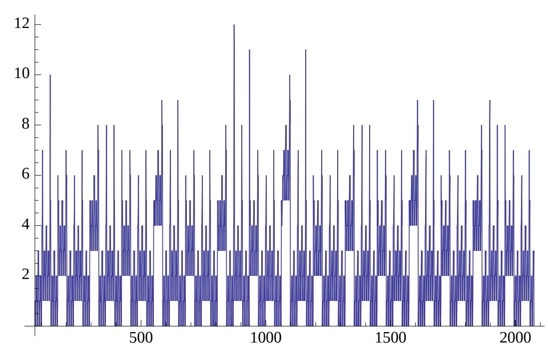

FIGURE 7. The data for $S(n,75)$

Section 6 gives a larger selection of these type of pictures.

Main conjecture. We describe an algorithm that leads to a first description of the function $\nu_2(S(n,k))$ as depicted in the graphs above. The conjecture is stated here and the special case $k=5$ is established in Section 4.

Definition 1.4. Let $k \in \mathbb{N}$ be fixed and $m \in \mathbb{N}$. Then for $0 \leq j < 2^m$ define

$$C_{m,j} := \{2^m i + j : \quad i \in \mathbb{N}\}. \tag{1.20}$$

The first value of the index i is the smallest one that yields $2^m i + j \geq k$. For example, for $k=5$ and $m=6$, we have

$$C_{6,28} = \{2^6 i + 28 : \quad i \geq 0\}. \tag{1.21}$$

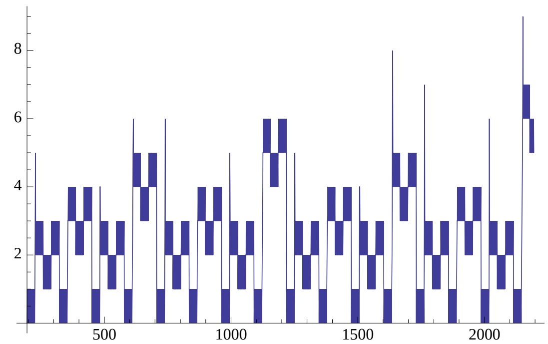

FIGURE 8. The data for $S(n, 195)$

We use the notation

$$\nu_2(C_{m,j}) = \{\nu_2\left(S(2^m i + j, k)\right) : \, i \in \mathbb{N}\}. \tag{1.22}$$

The classes $C_{m,j}$ form a partition of $\mathbb{N}$ into classes modulo 2^m. For example, for $m = 2$, we have the four classes

$$C_{2,0} = \{2^2 i : \, i \in \mathbb{N}\}, \qquad C_{2,1} = \{2^2 i + 1 : \, i \in \mathbb{N}\},$$
$$C_{2,2} = \{2^2 i + 2 : \, i \in \mathbb{N}\}, \qquad C_{2,3} = \{2^2 i + 3 : \, i \in \mathbb{N}\}.$$

The class $C_{m,j}$ is called *constant* if $\nu_2(C_{m,j})$ consists of a single value. This single value is called the constant of the class $C_{m,j}$.

For example, Corollary 3.3 shows that $\nu_2(S(4i+1, 5)) = 0$, independently of i. Therefore, the class $C_{2,1}$ is constant. Similarly, $C_{2,2}$ is constant with $\nu_2(C_{2,2}) = 0$.

We now introduce inductively the concept of *m-level*. For $m = 1$, the 1-level consists of the two classes

$$C_{1,0} = \{2i : \, i \in \mathbb{N}\} \text{ and } C_{1,1} = \{2i + 1 : \, i \in \mathbb{N}\}, \tag{1.23}$$

that is, the even and odd integers. Assume that the $m - 1$ level has been defined and it consists of the s classes

$$C_{m-1,i_1}, \, C_{m-1,i_2}, \, \cdots, C_{m-1,i_s}. \tag{1.24}$$

Each class C_{m-1,i_j} splits into two classes modulo 2^m, namely, C_{m,i_j} and $C_{m,i_j+2^{m-1}}$. The m-level is formed by the non-constant classes modulo 2^m.

Example 1.5. We describe the case of Stirling numbers $S(n, 10)$. Start with the fact that the 4-level consists of the classes $C_{4,7}$, $C_{4,8}$, $C_{4,9}$ and $C_{4,14}$. These split into the eight classes

$$C_{5,7}, \, C_{5,23}, \, C_{5,8}, \, C_{5,24}, \, C_{5,9}, \, C_{5,25}, \, C_{5,14}, \text{ and } C_{5,30},$$

modulo 32. Then one checks that $C_{5,23}$, $C_{5,24}$, $C_{5,25}$ and $C_{5,30}$ are all constant (with constant value 2 for each of them). The other four classes form the 5-level:

$$\{C_{5,7}, \, C_{5,8}, \, C_{5,9}, \, C_{5,14}\}. \tag{1.25}$$

We are now ready to state our main conjecture.

Conjecture 1.6. *Let $k \in \mathbb{N}$ be fixed. Then we conjecture that*

a) there exists a level $m_0(k)$ and an integer $\mu(k)$, such that, for any $m \geq m_0(k)$ the number of non-constant classes of level m is $\mu(k)$, independently of m,

b) moreover, for each $m \geq m_0(k)$, each of the $\mu(k)$ non-constant classes split into one constant and one non-constant in order to produce the next level.

Example 1.7. The conjecture is illustrated for $k = 11$. We claim that $m_0(11) = 3$ and $\mu(11) = 4$. The prediction is that for levels $m \geq 3$ we have four non-constant classes. Indeed, the classes $C_{2,0}$, $C_{2,1}$, $C_{2,2}$, $C_{2,3}$, have non-constant 2-adic valuation. Thus, every class in the 2-level split according to the diagram. To compute the next step, we observe that

$$\nu_2(C_{3,3}) = \nu_2(C_{3,5}) = \{0\} \text{ and } \nu_2(C_{3,4}) = \nu_2(C_{3,6}) = \{1\},$$

so there are four constant classes. The remaining four classes $C_{3,0}$, $C_{3,1}$, $C_{3,2}$ and $C_{3,7}$ form the 3-level. Observe that each of the four classes from the 2-level splits into a constant class and a class that forms part of the 3-level.

This process continues. At the next step, the classes of the 3-level split in two giving a total of 8 classes modulo 2^4. For example, $C_{3,2}$ splits into $C_{4,2}$ and $C_{4,10}$. The conjecture states that *exactly* one of these classes has constant 2-adic valuation. Indeed, the class $C_{4,2}$ satisfies $\nu_2(C_{4,2}) \equiv 2$ and $\nu_2(C_{4,10})$ is not constant.

Example 1.8. Figure 9 illustrates this process in the case $k = 7$. The first row of the figure shows the classes at level 2. The class $C_{2,0}$ has constant valuation $\nu_2(C_{2,0}) = 2$ and the class $C_{2,3}$ satisfies $\nu_2(C_{2,3}) = 0$. The remaining two classes, namely $C_{2,1}$ and $C_{2,3}$ form the second level that split into the pairs $\{C_{3,1}, C_{3,5}\}$ and $\{C_{3,2}, C_{3,6}\}$. In each pair we find a class of constant valuation and the second one, non-constant, that will be split to proceed with the diagram.

The diagram shows that $m_0(7) = 2$ and $\mu(7) = 2$.

Example 1.9. A case with a twist is $k = 13$. Level 3 has 8 classes and only 3 of them are constant (one expects half of them to be so). The five remaining classes split into 10 with 6 constants classes. At the next splitting, that is at level 5, we return to the expected count with 8 classes, half of which are non-constant. Thus, in this case, we have $m_0(13) = 5$ and $\mu(13) = 4$.

Elementary formulas. Throughout the paper we will use several elementary properties of $S(n,k)$, listed below:

- Relation to Pochhammer

$$x^n = \sum_{k=0}^{n} S(n,k)(x-k+1)_k, \tag{1.26}$$

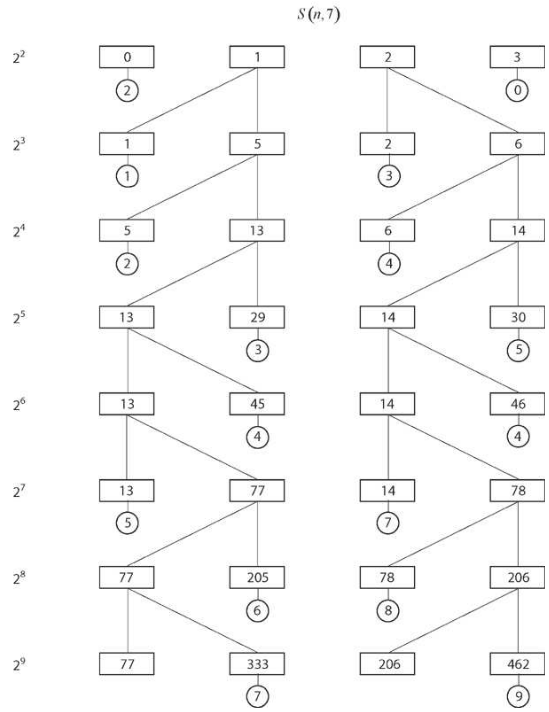

FIGURE 9. The splitting for $k = 7$

- An explicit formula

$$S(n,k) = \frac{1}{k!}\sum_{i=0}^{k-1}(-1)^i\binom{k}{i}(k-i)^n, \tag{1.27}$$

- The generating function

$$\frac{1}{(1-x)(1-2x)(1-3x)\cdots(1-kx)} = \sum_{n=1}^{\infty} S(n,k)x^n, \tag{1.28}$$

- The recurrence

$$S(n,k) = S(n-1,k-1) + kS(n-1,k) \tag{1.29}$$

Lengyel [9] conjectured, and De Wannemacker [12] proved, a special case of the 2-adic valuation of $S(n,k)$:

$$\nu_2\left(S(2^n,k)\right) = s_2(k) - 1, \tag{1.30}$$

independently of n. Here $s_2(k)$ is the sum of the binary digits of k. A numerical experiment suggests that

$$\nu_2\left(S(2^n+1,k+1)\right) = s_2(k) - 1, \tag{1.31}$$

is a companion of (1.30). In the general case, De Wannemacker [13] established the inequality

$$\nu_2\left(S(n,k)\right) \geq s_2(k) - s_2(n), \quad 0 \leq k \leq n. \tag{1.32}$$

The difference in (1.32) is more regular if $k-1$ is close to a power of 2. Figure 10 shows the (irregular) case $k = 101$ and Figure 11 shows the smoother case $k = 129$.

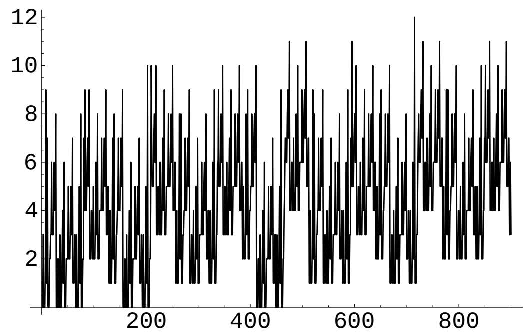

FIGURE 10. De Wannemacker difference for $k = 101$

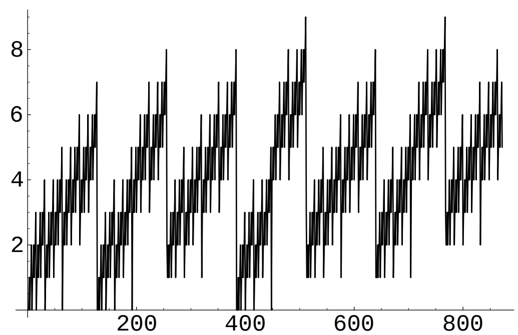

FIGURE 11. De Wannemacker difference for $k = 129$

2. THE ELEMENTARY CASES

This section presents, for sake of completeness, the 2-adic valuation of $S(n,k)$ for $1 \leq k \leq 4$. The arguments are all elementary.

Lemma 2.1. *The Stirling numbers of order* 1 *are given by* $S(n,1) = 1$, *for all* $n \in \mathbb{N}$. *Therefore*

$$\nu_2(S(n,1)) = 0. \tag{2.1}$$

Proof. There is a unique way to partition a set of n elements into one nonempty set: take them all. □

Lemma 2.2. *The Stirling numbers of order* 2 *are given by* $S(n,2) = 2^n - 1$, *for all* $n \in \mathbb{N}$. *Therefore*

$$\nu_2(S(n,2)) = 0. \tag{2.2}$$

Proof. The formula for $S(n,2)$ comes from (1.27). It can also be established by induction. Using the recurrence (1.29), and Lemma 2.1 we have

$$S(n,2) = S(n-1,1) + 2S(n-1,2) = 1 + 2(2^{n-1} - 1) = 2^n - 1.$$

□

Lemma 2.3. *The Stirling numbers of order* 3 *are given by*

$$S(n,3) = \tfrac{1}{2}(3^{n-1} - 2^n + 1). \tag{2.3}$$

Moreover

$$\nu_2(S(n,3)) = \begin{cases} 0 & \text{if } n \quad \text{is odd,} \\ 1 & \text{if } n \quad \text{is even.} \end{cases} \tag{2.4}$$

Proof. The expression for $S(n,3)$ comes from (1.27). An inductive proof also follows directly from the recurrence (1.29)

$$S(n,3) = S(n-1,2) + 3S(n-1,3) \tag{2.5}$$

and Lemma 2.2. To prove the expression for $\nu_2(S(n,3))$ we iterate the recurrence and obtain

$$2^n - 1 = S(n,3) - \sum_{k=1}^{N-1} 3^k(2^{n-k} - 1) - 3^N S(n-N,3), \tag{2.6}$$

and with $N = n-1$ we have

$$S(n,3) = 2^n - 1 - \sum_{k=1}^{n-2} 3^k(2^{n-k} - 1). \tag{2.7}$$

If n is odd, then $S(n,3)$ is odd and $\nu_2(S(n,3)) = 0$.

For n even, the recurrence (2.5) yields

$$S(n,3) = 2^{n-1} + 3 \cdot 2^{n-2} - 4 + 3^2 S(n-2,3). \tag{2.8}$$

As an inductive step, assume that $S(n-2,3) = 2T_{n-2}$, with T_{n-2} odd. Then (2.8) yields

$$\tfrac{1}{2}S(n,3) = 2^{n-2} + 3 \cdot 2^{n-3} + 3^2 T_{n-2} - 2, \tag{2.9}$$

and we conclude that $S(n,3)/2$ is an odd integer. Therefore $\nu_2(S(n,3)) = 1$ as claimed. □

We now present a second proof of this result using elementary properties of the valuation ν_2. In particular we use the ultrametric inequality

$$\nu_2(x_1 + x_2) \geq \text{Min}\,\{\nu_2(x_1),\, \nu_2(x_2)\,\}\,. \tag{2.10}$$

The inequality is strict unless $\nu(x_1) = \nu_2(x_2)$. This inequality is equivalent to (1.6).

Second proof of Lemma 2.3. The powers of 3 modulo 8 satisfy

$$3^m + 1 \equiv 2 + (-1)^{m+1} \bmod 8, \tag{2.11}$$

because $3^{2k} \equiv 1 \bmod 8$. Therefore $3^m + 1 = 8t + 3 + (-1)^{m+1}$, for some $t \in \mathbb{Z}$. Now

$$\nu_2(8t) = 3 + \nu_2(t) > \nu_2(3 + (-1)^{m+1}), \tag{2.12}$$

and the ultrametric inequality (2.10) yields

$$\nu_2(3^m + 1) = \nu_2(3 + (-1)^{m+1}) = \begin{cases} 2 & \text{if } m \text{ is odd,} \\ 1 & \text{if } m \text{ is even.} \end{cases} \tag{2.13}$$

The Stirling numbers $S(n, 3)$ are given by

$$2S(n, 3) = 3^{n-1} + 1 - 2^n, \tag{2.14}$$

and $\nu_2(2^n) = n > 2 \geq \nu_2(3^{n-1} + 1)$. We conclude that

$$\nu_2(S(n, 3)) = \nu_2(3^{n-1} + 1 - 2^n) - 1 = \nu_2(3^{n-1} + 1) - 1. \tag{2.15}$$

The result now follows from (2.13).

We now discuss the Stirling number of order 4.

Lemma 2.4. *The Stirling numbers of order* 4 *are given by*

$$S(n, 4) = \tfrac{1}{6}(4^{n-1} - 3^n - 3 \cdot 2^{n+1} - 1). \tag{2.16}$$

Moreover

$$\nu_2(S(n, 4)) = \begin{cases} 1 & \text{if } n \quad \text{is odd,} \\ 0 & \text{if } n \quad \text{is even.} \end{cases} \tag{2.17}$$

That is, $\nu_2(S(n, 4)) = 1 - \nu_2(S(n, 3))$.

Proof. The expression for $S(n, 4)$ comes from (1.27). To establish the formula for $\nu_2(S(n, 4))$ we use the recurrence (1.29) in the case $k = 4$:

$$S(n, 4) = S(n-1, 3) + 4S(n-1, 4). \tag{2.18}$$

For n even, the value $S(n-1, 3)$ is odd, so that $S(n, 4)$ is odd and $\nu_2(S(n, 4)) = 0$. For n odd, $S(n, 4)$ is even, since $S(n-1, 3)$ is even. The recurrence (2.18) is now written as

$$\tfrac{1}{2}S(n, 4) = \tfrac{1}{2}S(n-1, 3) + 2S(n-1, 4). \tag{2.19}$$

The value $\nu_2(S(n-1, 3)) = 1$ shows that the right hand side is odd, yielding $\nu_2(S(n, 4)) = 1$. □

3. The Stirling numbers of order 5

The elementary cases discussed in the previous section are the only ones for which the 2-adic valuation $\nu_2(S(n, k))$ is easy to compute. The graph in Figure 12 gives $\nu_2(S(n, 5))$ and we now explore its properties.

The explicit formula (1.27) yields an expression for $S(n, 5)$.

Lemma 3.1. *The Stirling numbers* $S(n, 5)$ *are given by*

$$S(n, 5) = \tfrac{1}{24}(5^{n-1} - 4^n + 2 \cdot 3^n - 2^{n+1} + 1). \tag{3.1}$$

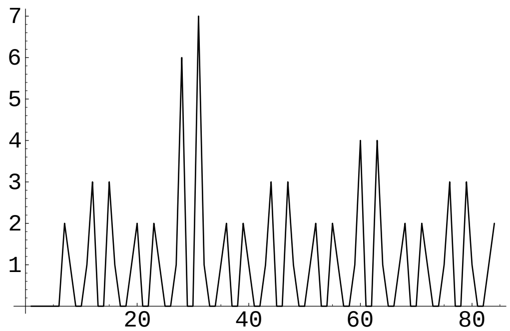

FIGURE 12. The 2-adic valuation of $S(n, 5)$

We now discuss the valuation $\nu_2(S(n,5))$. The 1-level consists of the two classes

$$1 - \text{level}: \quad \{C_{1,0},\, C_{1,1}\}. \tag{3.2}$$

These two classes split into $\{C_{2,0},\, C_{2,1},\, C_{2,2},\, C_{2,3}\}$ modulo 4. The parity of $S(n,5)$ determines two of them.

Lemma 3.2. *The Stirling numbers $S(n, 5)$ satisfy*

$$S(n,5) \equiv \begin{cases} 1 \mod 2 & \textit{if } n \equiv 1, \textit{ or } 2 \mod 4, \\ 0 \mod 2 & \textit{if } n \equiv 3, \textit{ or } 0 \mod 4. \end{cases} \tag{3.3}$$

Proof. The recurrence

$$S(n,5) = S(n-1,4) + 5S(n-1,5), \tag{3.4}$$

and the parity

$$S(n,4) \equiv \begin{cases} 1 \mod 2 & \text{if } n \equiv 0 \mod 2, \\ 0 \mod 2 & \text{if } n \equiv 1 \mod 2, \end{cases} \tag{3.5}$$

give the result by induction. □

Corollary 3.3. *The Stirling numbers $S(n, 5)$ satisfy*

$$\nu_2(S(4n+1,5)) = \nu_2(S(4n+2,5)) = 0, \textit{ for all } n \in \mathbb{N}. \tag{3.6}$$

The corollary states that the classes $C_{2,1}$ and $C_{2,2}$ are constant, so the 2 level is

$$2 - \text{level}: \quad \{C_{2,0},\, C_{2,3}\}. \tag{3.7}$$

This confirms part of the main conjecture; here $m_0 = 3$ in view of $2^2 < 5 \leq 2^3$ and the first level where we find constant classes is $m_0 - 1 = 2$.

Remark. Corollary 3.3 reduces the discussion of $\nu_2(S(n,5))$ to the indices $n \equiv 0$ or 3 mod 4. These two branches can be treated in parallel. Introduce the notation

$$q_n := \nu_2(S(n,5)), \tag{3.8}$$

and consider the table of values

$$X := \{q_{4i},\, q_{4i+3} \,:\, i \geq 2\}. \tag{3.9}$$

This starts as

$$X = \{1, 1, 3, 3, 1, 1, 2, 2, 1, 1, \mathbf{6}, \mathbf{7}, 1, 1, \ldots\}, \tag{3.10}$$

and after a while it continues as

$$X = \{\ldots, 1, 1, 2, 2, 1, 1, \mathbf{11}, \mathbf{6}, 1, 1, 2, 2, \ldots\}. \tag{3.11}$$

We observe that $q_{4i} = q_{4i+3}$ for most indices.

Definition 3.4. The index i is called *exceptional* if $q_{4i} \neq q_{4i+3}$.

The first exceptional index is $i = 7$ where $q_{28} = 6 \neq q_{31} = 7$. The list of exceptional indices continues as $\{7, 39, 71, 103, \ldots\}$.

Conjecture 3.5. *The set of exceptional indices is* $\{32j + 7 : j \geq 1\}$.

We now consider the class

$$C_{2,0} := \{q_{4i} = \nu_2(S(4i), 5) : i \geq 2\}, \tag{3.12}$$

where we have omitted the first term $S(4, 5) = 0$. The class $C_{2,0}$ starts as

$$C_{2,0} = \{1, 3, 1, 2, 1, 6, 1, 2, 1, 3, 1, 2, 1, 4, 1, 2, 1, 3, 1, 2, \ldots\}, \tag{3.13}$$

and it splits according to the parity of the index i into

$$C_{3,4} = \{q_{8i+4} : i \geq 1\} \text{ and } C_{3,0} = \{q_{8i} : i \geq 1\}. \tag{3.14}$$

The data suggests that $C_{3,0}$ is constant. This is easy to check.

Proposition 3.6. *The Stirling numbers of order* 5 *satisfy*

$$\nu_2(S(8i, 5)) = 1, \text{ for all } i \geq 1. \tag{3.15}$$

Proof. We analyze the identity

$$24S(8i, 5) = 5^{8i-1} - 4^{8i} + 2 \cdot 3^{8i} - 2^{8i+1} + 1 \tag{3.16}$$

modulo 32. Using $5^8 \equiv 1$ and $5^7 \equiv 13$ we obtain $5^{8i-1} \equiv 13$. Also $4^{8i} \equiv 2^{8i+1}$ mod 0. Finally $3^{8i} \equiv 81^{2i} \equiv 17^{2i} \equiv 1$. Therefore

$$5^{8i-1} - 4^{8i} + 2 \cdot 3^{8i} - 2^{8i+1} + 1 \equiv 16 \bmod 32. \tag{3.17}$$

We obtain that $24S(8i, 5) = 32t + 16$ for some $t \in \mathbb{N}$ and this yields $3S(8i, 5) = 2(2t + 1)$. Therefore $\nu_2(S(8i, 5)) = 1$. □

We now consider the class $C_{3,4}$.

Proposition 3.7. *The Stirling numbers of order* 5 *satisfy*

$$\nu_2(S(8i + 4, 5)) \geq 2, \text{ for all } i \geq 1. \tag{3.18}$$

Proof. We analyze the identity

$$24S(8i + 4, 5) = 5^{8i+3} - 4^{8i+4} + 2 \cdot 3^{8i+4} - 2^{8i+5} + 1 \tag{3.19}$$

modulo 32. Using $5^8 \equiv 1$, $5^3 \equiv 29$, $3^8 \equiv 1$, $3^4 \equiv 17$ and $2^4 \equiv 16$ modulo 32 we obtain

$$24S(8i + 4, 5) \equiv 0 \bmod 32. \tag{3.20}$$

Therefore $24S(8i+4, 5) = 32t$ for some $t \in \mathbb{N}$ and this yields $\nu_2(S(8i+4, 5) \geq 2$. □

Note. Lengyel [9] established that

$$\nu_2(k!S(n,k)) = k-1, \tag{3.21}$$

for $n = a2^q$, a is odd, and $q \geq k-2$. In the special case $k=5$ this yields $\nu_2(S(n,5)) = 1$ for $n = a2^q$ and $q \geq 3$. These values of n have the form $n = 8a \cdot 2^{q-3}$, so this is included in Proposition 3.6.

Remark. A similar argument yields

$$\nu_2(S(8i+3,5)) = 1 \text{ and } \nu_2(S(8i+7,5)) \geq 2. \tag{3.22}$$

We conclude that

$$3-\text{level}: \quad \{C_{3,4},\, C_{3,7}\}. \tag{3.23}$$

This confirms the main conjecture: each of the classes of the 2-level produces a constant class and a second one in the 3-level.

We now consider the class $C_{3,4}$ and its splitting as $C_{4,4}$ and $C_{4,12}$. The data for $C_{3,4}$ starts as

$$C_{3,4} = \{3,\, 2,\, 6,\, 2,\, 3,\, 2,\, 4,\, 2,\, 3,\, 2,\, 5,\, 2,\, 3,\, 2,\, 4,\, 2,\, 3,\, 2,\, 11,\, 2,\, 3,\, 2,\, \ldots\}. \tag{3.24}$$

This suggests that the values with even index are all 2. This can be verified.

Proposition 3.8. *The Stirling numbers of order* 5 *satisfy*

$$\nu_2(S(16i+4,5)) = 2, \ \textit{for all } \geq 1. \tag{3.25}$$

Proof. We analyze the identity

$$24S(16i+4,5) = 5^{16i+3} - 4^{16i+4} + 2 \cdot 3^{16i+4} - 2^{16i+5} + 1 \tag{3.26}$$

modulo 64. Using $5^{16} \equiv 1$, $5^3 \equiv 61$, $3^{16} \equiv 1$ and $3^4 \equiv 17$ we obtain

$$5^{16i+3} - 4^{16i+4} + 2 \cdot 3^{16i+4} - 2^{16i+5} + 1 \equiv 32 \bmod 64. \tag{3.27}$$

Therefore $24S(16i+4,5) = 64t+32$ for some $t \in \mathbb{N}$. This gives $3S(16i+4,5) = 4(2t+1)$ and it follows that $\nu_2(S(16i+4,5)) = 2$. □

Note. A similar argument shows that $\nu_2(S(16i+12,5)) \geq 3$ and also $\nu_2(S(16i+7,5)) = 2$ and $\nu_2(S(16i+15,5)) \geq 3$. Therefore the 4-level is $\{C_{4,12},\, C_{4,15}\}$.

This splitting process of the classes can be continued and, according to our main conjecture, the number of elements in the m-level is always constant. To prove the statement similar to Propositions 3.6 and 3.8 requires us to analyze the congruence

$$24S(2^mi+j,5) \equiv 5^{2^mi+j-1} - 4^{2^mi+j} + 2 \cdot 3^{2^mi+j} - 2^{2^mi+j+1} + 1 \bmod 2^{m+2}. \tag{3.28}$$

This can be done for a specific choice of j, those giving the indices at the m-level. At the moment we cannot predict which values of j will appear at the m-level. We present a proof of this conjecture, for the special case $k=5$, in the next section.

Problem. Is there a combinatorial mechanism that enables us to make such a binary choice for each m-level split class?

Lundell [11] studied the Stirling-like numbers

$$T_p(n,k) = \sum_{j=0}^{k} (-1)^{k-j} \binom{k}{j} j^n, \tag{3.29}$$

where the prime p is fixed and the index j is omitted in the sum if it is divisible by p. Clarke [5] conjectured that

$$\nu_p(k!\, S(n,k)) = \nu_p(T(n,k)). \tag{3.30}$$

From this conjecture he derives an expression for $\nu_2(S(n,5))$ in terms of the zeros of the form $f_{0,5}(x) = 5 + 10 \cdot 3^x + 5^x$ in the ring of 2-adic integers $\mathbb{Z}_2$.

Theorem 3.9. *Let u_0 and u_1 be the 2-adic zeros of the function $f_{0,5}$. Then, under the assumption that conjecture (3.30) holds, we have*

$$\nu_2(S(n,5)) = \begin{cases} -1 + \nu_2(n-u_0) & \text{if } n \text{ is even,} \\ -1 + \nu_2(n-u_1) & \text{if } n \text{ is odd.} \end{cases} \tag{3.31}$$

Here u_0 is the unique zero of $f_{0,5}$ that satisfies $u_0 \in 2\mathbb{Z}_2$ and u_1 is the other zero of $f_{0,5}$ and satisfies $u_1 \in 1 + 2\mathbb{Z}_2$.

Clarke also obtained in [5] similar expressions for $\nu_2(S(n,6))$ and $\nu_2(S(n,7))$ in terms of zeros of the functions

$$f_{0,6} = -6 - 20 \cdot 3^x - 6 \cdot 5^x \text{ and } f_{0,7} = 7 + 35 \cdot 3^x + 21 \cdot 5^x + 7^x.$$

4. Proof of the main conjecture for $k = 5$

The goal of this section is to prove the main conjecture in the case $k = 5$. The parameter m_0 is 3 in view of $2^2 < 5 \leq 2^3$. In the previous section we have verified that $m_0 - 1 = 2$ is the first level for constant classes. We now prove this splitting of classes.

Theorem 4.1. *Assume $m \geq m_0$. Then the m-level consists of exactly two split classes: $C_{m,j}$ and $C_{m,j+2^{m-1}}$. They satisfy $\nu_2(C_{m,j}) > m-3$ and $\nu_2(C_{m,j+2^{m-1}}) > m-3$. Then exactly one, call it C^1, satisfies $\nu_2(C^1) = \{m-2\}$ and the other one, call it C^2, satisfies $\nu_2(C^2) > m-2$.*

The proof of this theorem requires several elementary results of 2-adic valuations.

Lemma 4.2. *For $m \in \mathbb{N}$: $\nu_2\left(5^{2^m} - 1\right) = m + 2$.*

Proof. Start at $m = 1$ with $\nu_2(24) = 3$. The inductive step uses

$$5^{2^{m+1}} - 1 = (5^{2^m} - 1) \cdot (5^{2^m} + 1).$$

Now $5^k + 1 \equiv 2 \bmod 4$ so that $5^{2^m} + 1 = 2\alpha_1$ with α_1 odd. Thus

$$\nu_2(5^{2^{m+1}} - 1) = \nu_2(5^{2^m} - 1) + \nu_2(5^{2^m} + 1) = (m+2) + 1 = m + 3.$$

□

The same type of argument produces the next lemma.

Lemma 4.3. *For $m \in \mathbb{N}$: $\nu_2(3^{2^m} - 1) = m + 2$.*

Lemma 4.4. *For $m \in \mathbb{N}$: $\nu_2(5^{2^m} - 3^{2^m}) = m + 3$.*

Proof. The inductive step uses

$$5^{2^{m+1}} - 3^{2^{m+1}} = (5^{2^m} - 3^{2^m}) \times \left((5^{2^m} - 1) + (3^{2^m} + 1) \right).$$

Therefore $\nu_2(5^{2^m} - 1) = m + 2$ and $3^{2^m} \equiv 1 \bmod 4$, thus $\nu_2(3^{2^m} + 1) = 1$. We conclude that

$$\nu_2((5^{2^m} - 1) + (3^{2^m} + 1)) = \text{Min}\{m + 2, 1\} = 1.$$

We obtain

$$\nu_2(5^{2^{m+1}} - 3^{2^{m+1}}) = m + 4, \tag{4.1}$$

and this concludes the inductive step. □

The recurrence (1.29) for the Stirling numbers $S(n, 5)$ is

$$S(n, 5) = 5S(n-1, 5) + S(n-1, 4). \tag{4.2}$$

Iterating this result yields the next lemma.

Lemma 4.5. *Let $t \in \mathbb{N}$. Then*

$$S(n, 5) - 5^t S(n-t, 5) = \sum_{j=0}^{t-1} 5^j S(n-j-1, 4). \tag{4.3}$$

Proof of theorem 4.1. We have already checked the conjecture for the 2-level. The inductive hypothesis states that the $(m-1)$-level survivor has the form

$$C_{m,k} = \{\nu_2(S(2^m n + k, 5)) : \, n \geq 1\} \tag{4.4}$$

and that $\nu_2(S(2^m n + k, 5)) > m - 2$. At the next level this class splits into the two classes

$$\begin{aligned} C_{m+1,k} &= \{\nu_2(S(2^{m+1} n + k, 5)) : \, n \geq 1\} \quad \text{and} \\ C_{m+1,k+2^m} &= \{\nu_2(S(2^{m+1} n + k + 2^m, 5)) : \, n \geq 1\}, \end{aligned}$$

and every element of each of these two classes is greater or equal than $m - 1$.

We now prove that one of these classes reduces to the singleton $\{m - 1\}$ and that every element in the other class is strictly greater than $m - 1$.

The first step is to use Lemma 4.5 to compare the values of $S(2^{m+1}n + k, 5)$ and $S(2^{m+1}n + k + 2^m, 5)$. Define

$$M = 2^m - 1 \text{ and } N = 2^{m+1}n + k; \tag{4.5}$$

then we have

$$S(2^{m+1}n + k + 2^m, 5) - 5^{2^m} S(2^{m+1}n + k, 5) = \sum_{j=0}^{M} 5^{M-j} S(N + j, 4). \tag{4.6}$$

Proposition 4.6. *With the notation as above,*

$$\nu_2 \left(\sum_{j=0}^{M} 5^{M-j} S(N + j, 4) \right) = m - 1. \tag{4.7}$$

Proof. The explicit formula (1.27) yields

$$6S(n,4) = 4^{n-1} + 3\cdot 2^{n-1} - 3^n - 1. \tag{4.8}$$

Thus

$$\begin{aligned} 6\sum_{j=0}^{M} 5^{M-j} S(N+j,4) &= 4^{N-1}(5^{M+1}-4^{M+1}) + 2^{N-1}(5^{M+1}-2^{M+1}) \\ &\quad -3^N \times \tfrac{1}{2}(5^{M+1}-3^{M+1}) - \tfrac{1}{4}(5^{M+1}-1). \end{aligned}$$

The results in Lemmas 4.2, 4.3 and 4.4 yield

$$6\sum_{j=0}^{M} 5^{M-j} S(N+j,4) = 4^{N-1}\alpha_1 + 2^{N-1}\alpha_2 - 3^N\cdot 2^{m+2}\alpha_3 - 2^m\alpha_4 \tag{4.9}$$

with α_j odd integers. Write this as

$$6\sum_{j=0}^{M} 5^{M-j} S(N+j,4) = 2^{N-1}\left(2^{N-1}\alpha_1+\alpha_2\right) - 2^m\left(4\alpha_3 3^N + 1\right) \equiv T_1 + T_2.$$

Then $\nu_2(T_1) = N-1 > m = \nu_2(T_2)$ and we obtain

$$\nu_2\left(\sum_{j=0}^{M} 5^{M-j} S(N+j,4)\right) = m-1. \tag{4.10}$$

We conclude that

$$S(2^{m+1}n+k+2^m,5) - 5^{2^m} S(2^{m+1}n+k,5) = 2^{m-1}\alpha_5, \tag{4.11}$$

with α_5 odd. Define

$$X := 2^{-m+1}S(2^{m+1}n+k+2^m,5) \text{ and } Y := 2^{-m+1}S(2^{m+1}n+k,5). \tag{4.12}$$

Then X and Y are integers and $X - Y \equiv 1 \bmod 2$, so that they have opposite parity. If X is even and Y is odd, we obtain

$$\nu_2\left(S(2^{m+1}n+k+2^m,5)\right) > m-1 \text{ and } \nu_2\left(S(2^{m+1}n+k,5)\right) = m-1. \tag{4.13}$$

The case X odd and Y even is similar. This completes the proof. □

5. Some approximations

In this section we present some approximations to the function $\nu_2(S(n,5))$. These approximations were derived empirically and they support our belief that 2-adic valuations of Stirling numbers can be well approximated by simple integer combinations of the most basic 2-adic valuations of the integers.

For each prime p, define

$$\lambda_p(m) = \frac{1}{2}\left(1-(-1)^{m \bmod p}\right). \tag{5.1}$$

First approximation. Define

$$f_1(m) := \lfloor \frac{m+1}{2} \rfloor + 112\lambda_2(m) + 50\lambda_2(m+1). \tag{5.2}$$

Then $\nu_2(S(m,5))$ and $\nu_2(f_1(m))$ agree for most values. The first time they differ is at $m = 156$ where

$$\nu_2(S(156,5)) - \nu_2(f_1(156)) = 4.$$

The first few indices for which $\nu_2(S(m,5)) \neq \nu_2(f_1(m))$ are $\{156, 287, 412, 668, 799, \ldots\}$.

Conjecture 5.1. *Define*

$$x_1(m) = 156 + 125\lfloor \frac{4m}{3} \rfloor + 6\lfloor \frac{2m+1}{3} \rfloor \tag{5.3}$$

and

$$I_1 = \{x_1(m) : m \geq 0\}. \tag{5.4}$$

Then $\nu_2(S(m,5)) = \nu_2(f_1(m))$ *unless* $m \in I_1$.

The parity of the exceptions in I_1 is easy to establish: every third element is odd and the even indices of I_1 are on the arithmetic progression $256m + 156$.

Second approximation. We now describe a new approximation to the error

$$\text{Err}_2(m,5) := \nu_2(S(m,5)) - \nu_2(f_1(m)). \tag{5.5}$$

Define

$$\begin{aligned} m_3(m) &:= (m+2) \mod 3, \\ \alpha_m &:= \lambda_3(m+2)\,(1+\lambda_3(m)) + \lambda_2(m+1)\lambda_3(m). \end{aligned}$$

Now define

$$f_2(m) = \binom{2m_3}{m_3} \lfloor \frac{m+2}{3} \rfloor + 208\lambda_3(m+1) + 27\lambda_2(m)\lambda_3(m). \tag{5.6}$$

The next conjecture improves the prediction of Conjecture 5.1.

Conjecture 5.2. *Define*

$$Err_2(x_1(m)) := \nu_2(S(x_1(m),5) - (-1)^{\alpha_m}\nu_2(f_2(m)), \tag{5.7}$$

and

$$x_2(m) = 109 + 107\lfloor \frac{4m+2}{3} \rfloor + 85\lfloor \frac{4m+1}{3} \rfloor. \tag{5.8}$$

Finally, let $I_2 = \{x_2(m) : m \geq 0\}$. *Then* $Err_2(m) = 0$ *unless* $m \in I_2$.

There is single class per level that we write as

$$C_{m,j} = \{q_{2^m i + j} : i \in \mathbb{N}\}, \tag{5.9}$$

where $j = j(m)$ is the index that corresponds to the non-constant class at the m-level. The first few examples are listed below.

$$\begin{aligned} C_{2,4} &= \{q_{4i+4} : i \in \mathbb{N}\} \\ C_{3,4} &= \{q_{8i+4} : i \in \mathbb{N}\} \\ C_{4,12} &= \{q_{16i-4} : i \in \mathbb{N}\} \\ C_{5,28} &= \{q_{32i-4} : i \in \mathbb{N}\} \\ C_{6,28} &= \{q_{64i-36} : i \in \mathbb{N}\} \\ C_{7,156} &= \{q_{128i-100} : i \in \mathbb{N}\} \\ C_{8,156} &= \{q_{256i-100} : i \in \mathbb{N}\} \\ C_{9,156} &= \{q_{512i-356} : i \in \mathbb{N}\} \\ C_{10,156} &= \{q_{1024i-868} : i \in \mathbb{N}\} \end{aligned}$$

We have observed a connection between the indices $j(m)$ and the set of exceptional indices I_1 in (5.4).

Conjecture 5.3. *Construct a list of numbers* $\{c_i : i \in \mathbb{N}\}$ *according to the following rules. Let* $c_1 = 8$ *(the first index in the class* $C_{2,4}$*), and then define* c_j *as the first value on* $C_{m,j}$ *that is strictly bigger than* c_{j-1}*. The set* C *begins as*

$$C = \{8,\ 12,\ 28,\ 60,\ 92,\ 156,\ 412,\ 668,\ 1180, \ldots\}. \tag{5.10}$$

Then, starting at 156*, the number* $c_i \in I_1$*.*

6. A sample of pictures

In this section we present data that illustrate the wide variety of behavior for the 2-adic valuation of Stirling numbers $S(n,k)$.
